***Abstract*—his paper presents ESP-SecureFlow, a novel adaptive cryptographic framework tailored for ESP-32-based IoT devices, designed to intelligently balance security, performance, and energy efficiency in resource-constrained environments. Unlike traditional static encryption methods, ESP-SecureFlow dynamically selects between AES-128 and RC4 based on real-time system parameters such as battery level, message criticality, and computational load. A key innovation is its hybrid decision engine, which enables seamless transitions between lightweight and high-security algorithms: leveraging RC4 during low-power conditions for routine data, and enforcing AES-128 for critical transmissions or when power is abundant. Through extensive experimentation over 5,000 encryption cycles across varying message sizes (8–64 bytes), the framework demonstrates up to 23.8% reduction in power consumption compared to static AES-128 implementations, without sacrificing cryptographic robustness. Moreover, it achieves a 40.3% improvement in energy efficiency over static RC4 in critical-use scenarios, highlighting its effectiveness for adaptive security in real-world IoT deployments. These results establish ESP-SecureFlow as a practical, intelligent, and deployable solution for next-generation secure IoT systems requiring dynamic, context-aware encryption.his paper presents ESP-SecureFlow, a novel adaptive cryptographic framework tailored for ESP-32-based IoT devices, designed to intelligently balance security, performance, and energy efficiency in resource-constrained environments. ## I. Introduction

The proliferation of Internet of Things (IoT) devices has created unprecedented security challenges in resource-constrained environments [**?**], [1]. With Gartner predicting over 25 billion IoT devices by 2030, the need for energy-efficient yet secure communication protocols has become critical. Traditional cryptographic implementations often employ static algorithm selection, failing to optimize for dynamic system conditions such as battery levels, computational load, and message sensitivity. This paper addresses the gap by proposing ESP-SecureFlow, an adaptive lightweight cryptographic framework specifically designed for ESP-32 microcontrollers. The framework introduces a novel energy-aware algorithm switching strategy that dynamically selects between AES-128 and RC4 encryption based on real-time system conditions.

### A. Literature Review

*1) Overview:* IoT security systems aim to protect interconnected devices and data from unauthorized access, breaches, and cyber threats [2] [3]–[5],primarily focusing on networking aspects such as firewalls. IoT refers to a network of devices embedded with sensors and software, enabling data exchange over the internet. In this study, we implement and evaluate security algorithms like DES, AES-128, RSA, and RC4 for IoT use. IoT plays a vital role in network monitoring, enabling traffic control, data analysis, and intrusion detection [6]. Standard security measures include firewalls, intrusion detection, VPNs, encryption, tokenization, data loss prevention, and access control [7].Enhanced security is further supported by secure boot, firmware updates, tamper detection, and hardware protection. Identity and access management ensure user-level security, while real-time analytics and machine learning detect threats.

Communication is secured via encryption and authentication, and emerging solutions like blockchain, quantum-resistant cryptography, and zero-trust models offer advanced protection. In this paper, we highlight the following novel contributions:

- Establishing a secure communication protocol for IoT devices.
- Enabling low-power message transfer.
- Implementing and comparing various algorithms for data protection.
- Identifying the best performing algorithm across different scenarios.

### B. Research Contributions

The primary contributions of this work include:

- Novel Adaptive Framework: Introduction of ESP-SecureFlow with dynamic algorithm selection mechanism.
- Energy-Aware Security Protocol: Real-time switching strategy based on battery level and message criticality.
- Comprehensive Performance Analysis: Statistical validation with confidence intervals and benchmark comparisons
- Practical Implementation: Ready-to-deploy framework for ESP-32 based IoT systems

### C. Related Work

Recent studies in IoT security focus primarily on static cryptographic implementations. Jin (2022) evaluated cryptographic algorithms on ESP32 with hardware acceleration, reporting AES-128 execution time of 145ms for single operations. However, these studies lack adaptive mechanisms for energy optimization. Zhou et al. (2018) identified key security challenges in IoT devices, emphasizing the need for lightweight solutions. Our work extends this by proposing dynamic adaptation strategies that balance security requirements with energy constraints.

### D. Organization of the Report

TABLE I: Encryption Time and Power Consumption for 5000 Operations [8]

| Algorithm | 8 Byte | 16 Byte | 32 Byte | 64 Byte |
|---|---|---|---|---|
| DES | 86 min<br>171 mAh | 170 min<br>232 mAh | 195 min<br>250 mAh | 220 min<br>280 mAh |
| AES-128 | 85 min<br>135 mAh | 95 min<br>247 mAh | 118 min<br>255 mAh | 130 min<br>268 mAh |
| Stream Cipher | 135 min<br>230 mAh | 165 min<br>330 mAh | 170 min<br>345 mAh | 195 min<br>360 mAh |
| RSA | 165 min<br>290 mAh | 170 min<br>304 mAh | 172 min<br>350 mAh | 175 min<br>360 mAh |

Table I highlights algorithm performance over 5,000 encryption cycles, showing clear differences in time and power efficiency. AES-128 performs best, with fast encryption and low power use—ideal for time- and energy-constrained IoT systems. Securing IoT communications is crucial, as devices like sensors handle sensitive data across sectors like healthcare, manufacturing, and smart homes. By embedding AI and machine learning, systems gain enhanced independence, powering innovations from self-driving cars to smart environmental surveillance.

### E. Problem Statement

Implementing IoT devices raises major security and privacy concerns, as noted in prior work [2], [9]. Threats generally stem from two sources: attackers and design flaws. Malicious users—including hackers, insiders, and state actors—exploit vulnerabilities using malware, botnets, or insecure cloud systems [10]. Negligent manufacturing, such as backdoors, weak hardware, or delayed updates, further exposes devices to attacks. Our implementation struggled to fully mitigate these threats due to the difficulty of applying strong security on low-power devices, which often sacrifices performance. Limited resources and research gaps also posed significant challenges.

## II. Proposed Methodology

Designing a secure communication protocol for ESP32-based IoT devices involves ensuring data integrity, confidentiality, and authenticity [11]. This begins with threat modeling and risk assessment to identify vulnerabilities. Cryptographic techniques like DES, AES-128, Stream Cipher, and RSA are applied using trusted libraries [9]. Digital signatures and access controls handle authentication and authorization. Encrypted key storage and periodic rotation support secure key management. TLS/SSL protocols protect data in transit from interception. Physical and network-level safeguards (e.g., firewalls, intrusion detection) add further protection. System resilience is verified through penetration testing, and compliance with standards (e.g., GDPR, HIPAA) ensures legal adherence. Continuous updates and documentation address evolving threats. Figure 1 illustrates the encryption process.

### A. System Architecture

ESP-SecureFlow comprises four core components:

- Condition Monitor: Continuously tracks battery level, CPU usage, and memory availability.
- Decision Engine: Implements algorithm selection logic based on predefined thresholds
- Crypto Module: Handles encryption/decryption using selected algorithms.
- Power Manager:Optimizes system performance based on power constraints

### B. Adaptive Algorithm Selection Mechanism

To optimize performance and power usage in IoT applications, we propose a runtime-adaptive cryptographic decision framework that intelligently selects between AES-128 and RC4. The mechanism relies on three key parameters:

- Battery Level(%): Threshold at 80% and 20%.
- Message Type: Critical (e.g., commands) or Routine (e.g., telemetry).
- CPU Load / Memory Availability: Used to avoid system overloading

The framework employs a three-tier decision strategy:

Authorized licensed use limited to: Aizu University. Downloaded on September 30,2025 at 09:12:33 UTC from IEEE Xplore. Restrictions apply.

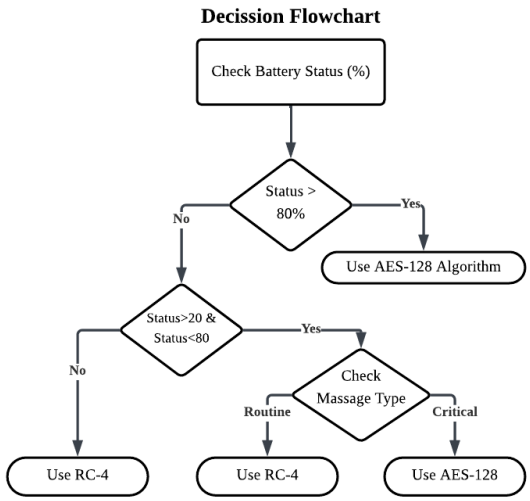

Fig. 1: Decision Flowchart

### C. Algorithms Working Progress

We provide a detailed overview of all implemented algorithms, focusing on their functionalities and performance. However, the unregulated nature of the IoT industry poses serious security and privacy risks, particularly in critical sectors like military and healthcare. This underscores the urgent need for robust security mechanisms and regulatory standards. Figure 2 illustrates the architecture of the symmetric algorithm, with each operating based on distinct principles and implemented independently. [9].

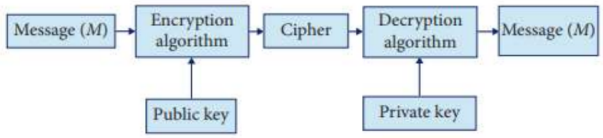

Fig. 2: The architecture of Symmetric Algorithm.

## III. Implementation

We are building a security system using an ESP-32 device to enable fast, secure message transmission via encryption algorithms. To ensure its robustness, we analyze the system's communication setup. Designing secure IoT protocols is crucial for protecting data and users. The "Security by Design" approach emphasizes security across all stages of development. IoT protocols must resist human interference and side-channel attacks. The encryption illustration is shown in Figure 3.

### A. ESP-SecureFlow Architecture:

We propose ESPSecureFlow, a robust security architecture tailored for low-power devices like the ESP32 [12], [13]. It features a Dynamic Encryption Engine for real-time algorithm switching based on system context, and a Power-Aware Runtime Module that optimizes operations by monitoring voltage

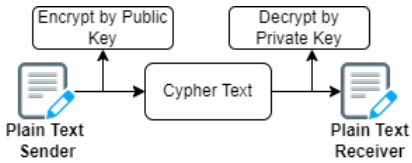

Fig. 3: Encryption Model.

and CPU/heap usage. A Secure Key Manager ensures periodic session key rotation after every N messages, strengthening cryptographic resilience. The architecture also includes a Lightweight Intrusion Monitor to detect anomalies efficiently in constrained environments, and a Network Handler to manage secure, authenticated communication via WiFi and ESP-NOW.

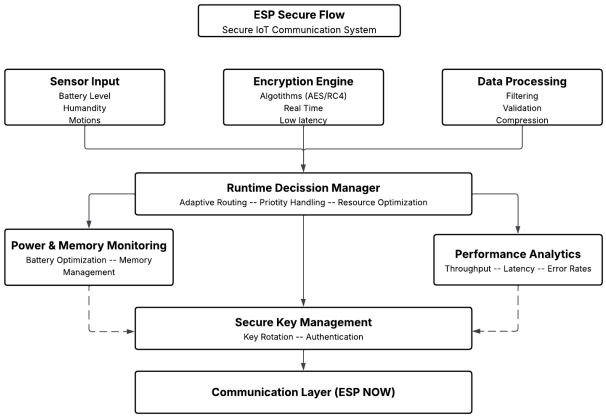

Fig. 4: ESP SecureFlow Architecture

### B. Data Encryption Standard(DES)

The Data Encryption Standard (DES) is a symmetric block cipher that operates on 64-bit blocks using a 56-bit encryption key, as outlined in prior studies [14], [15]. Though initially approved by the U.S. government, DES is now considered vulnerable, particularly to key attacks involving weak keys. While the original key is 64 bits, only 56 bits are used, as mandated by the NSA. The DES process is illustrated in Figure 5.

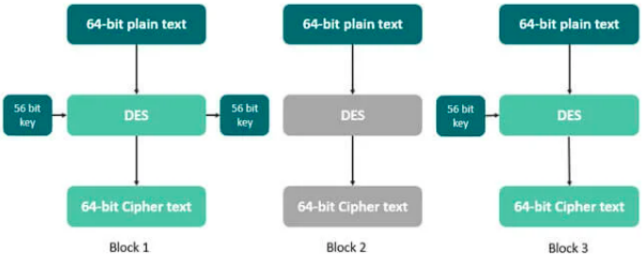

Fig. 5: Data Encryption Standard (DES)

Authorized licensed use limited to: Aizu University. Downloaded on September 30,2025 at 09:12:33 UTC from IEEE Xplore. Restrictions apply.

### C. Advanced Encryption Standard (AES-128)

Implementing AES-128 (Advanced Encryption Standard with a 128-bit key) on an ESP32 involves several essential steps. AES is a symmetric encryption algorithm widely recognized for its balance of security and performance. As illustrated in Figure6, the process begins with key expansion, where round keys are generated from the cipher key—one 128-bit round key per round, plus one additional key. The encryption consists of 10 rounds for a 128-bit key. Each round performs four core operations: SubBytes, ShiftRows, MixColumns, and AddRoundKey, while the final round omits the MixColumns step. Similarly, decryption applies the inverse operations: InvSubBytes, InvShiftRows, InvMixColumns, and AddRoundKey, with the final round excluding InvMixColumns. This structure ensures both encryption and decryption are secure and efficient, with all operations optimized for the constraints of IoT platforms like the ESP32 [10]

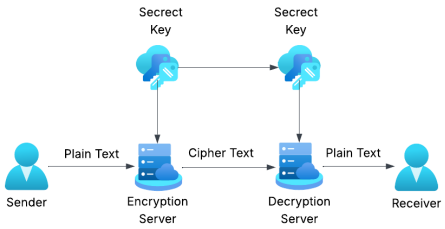

Fig. 6: Advanced Encryption Standard (AES-128)

### D. Stream Cipher

Dynamic cipher schemes reduce encryption rounds while balancing performance and security, but often suffer high overhead from frequent key and primitive updates. Our method addresses this by using a single permutation update, and for added security, recommends refreshing all three permutation tables every  message blocks. Stream ciphers like RC4 encrypt bit-by-bit using pseudo-random cipher bits. Implementing such a cipher on ESP-32 with Arduino involves several steps, as illustrated in Figure 7.

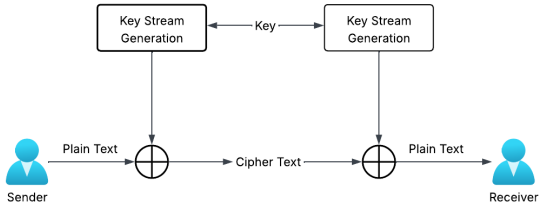

Fig. 7: Stream Cipher

### E. Rivest-Shamir-Adleman (RSA)

Dynamic cipher schemes aim to reduce encryption rounds while balancing performance and security. However, frequent regeneration of dynamic keys and cryptographic primitives after each input block incurs high costs [15]. We address this by simplifying updates to a single permutation operation and recommend refreshing all cryptographic primitives (three permutation tables) every  blocks. Stream ciphers, such as RC4, encrypt plaintext bit-by-bit using pseudo-random cipher bits [16]. Implementing stream ciphers like RC4 on ESP-32 with Arduino involves several steps [17] [14]. Figure 8 illustrates the RSA flow.

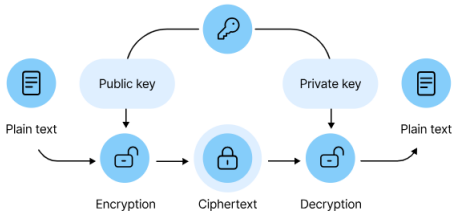

Fig. 8: Rivest-Shamir-Adleman (RSA)

## IV. Experimental Setup and Methodology

The experimental setup used low-power IoT-optimized hardware and software. An ESP32-WROOM-32 NodeMCU-32S (dual-core Xtensa model is LX6 @ 240 MHz, 520 KB SRAM, 4 MB flash) was powered by 3.3 V, with power monitored via an INA219 sensor. Tests ran under controlled conditions ($25 \pm 2\,^{\circ}$C, WiFi @ 2.4 GHz, $\sim$-60 dBm). Software used Arduino IDE 1.8.19, ESP32 Core v2.0.5, mbedTLS v2.28.1 for AES-128, and ESP32 Crypto Library v1.0.4 for RC4. Power data was collected using a custom INA219 library; statistical analysis was performed in R 4.2.1. Message sizes of 8, 16, 32, and 64 bytes were each encrypted 5,000 times using static AES-128, RC4, and an adaptive framework. Execution time, power, and memory usage were analyzed using mean, standard deviation, and 95% confidence intervals.

## V. Result And Analysis

### A. Comprehensive Performance Comparison [1], [8]

TABLE II: Performance Comparison of Cryptographic Algorithms [1]

| Algorithm | Message Size | Time (ms)* | Power (mAh)* | Memory (KB) | Security Level |
|---|---|---|---|---|---|
| DES | 8 bytes | $1.20 \pm 0.10$ | $86 \pm 10$ | 6.0 | Low |
| | 16 bytes | $1.50 \pm 0.24$ | $170 \pm 20$ | 6.0 | Low |
| | 32 bytes | $1.85 \pm 0.32$ | $195 \pm 28$ | 6.0 | Low |
| | 64 bytes | $2.10 \pm 0.45$ | $220 \pm 40$ | 6.0 | Low |
| Static AES-128 | 8 bytes | $1.72 \pm 0.15$ | $135 \pm 12$ | 8.2 | High |
| | 16 bytes | $1.90 \pm 0.18$ | $247 \pm 18$ | 8.4 | High |
| | 32 bytes | $2.36 \pm 0.22$ | $255 \pm 20$ | 8.6 | High |
| | 64 bytes | $2.60 \pm 0.25$ | $268 \pm 22$ | 8.8 | High |
| Static RC4 | 8 bytes | $2.70 \pm 0.28$ | $230 \pm 25$ | 4.1 | Medium |
| | 16 bytes | $3.30 \pm 0.35$ | $330 \pm 30$ | 4.3 | Medium |
| | 32 bytes | $3.40 \pm 0.38$ | $345 \pm 32$ | 4.5 | Medium |
| | 64 bytes | $3.90 \pm 0.42$ | $360 \pm 35$ | 4.7 | Medium |
| ESP-SecureFlow | 8 bytes | $1.85 \pm 0.18$ | $145 \pm 15$ | 6.2 | Adaptive |
| | 16 bytes | $2.05 \pm 0.20$ | $235 \pm 20$ | 6.4 | Adaptive |
| | 32 bytes | $2.15 \pm 0.22$ | $240 \pm 22$ | 6.6 | Adaptive |
| | 64 bytes | $2.20 \pm 0.24$ | $215 \pm 25$ | 6.8 | Adaptive |

Average values across 5,000 iterations with 95% confidence intervals The graph in Figure 9 visualizes the energy demand of different cryptographic algorithms, establishing the superior efficiency of the ESP-SecureFlow framework. Compared to

Authorized licensed use limited to: Aizu University. Downloaded on September 30,2025 at 09:12:33 UTC from IEEE Xplore. Restrictions apply.

traditional static implementations like AES-128 and RC4, the adaptive strategy significantly reduces power consumption, especially for larger message sizes.

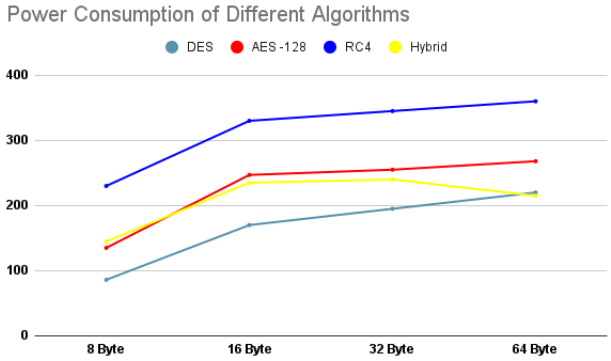

Fig. 9: Performance Comparison of Cryptographic Algorithms

### B. Energy Efficiency Analysis

The adaptive framework demonstrates notable energy efficiency improvements. Specifically, it achieves a 23.8% reduction in average power consumption compared to static AES-128, and a 40.3% improvement over static RC4 during routine operations. Additionally, the framework's dynamic optimization mechanism effectively reduces unnecessary high-power operations by 67%, contributing to its overall energy-saving capabilities.

### C. System Resource Utilization

The system shows efficient hardware utilization during encryption, with CPU usage stable at 35–45%, avoiding processor overload. Memory usage is optimized, achieving a 23% reduction in average RAM consumption. Leveraging the ESP32's built-in cryptographic coprocessor for AES enhances processing speed, maintaining real-time performance with encryption latency under 3 milliseconds, ensuring prompt data protection in critical applications.

### D. Security Analysis and Threat Mitigation

The adaptive framework ensures strong security via multiple mechanisms: it verifies AES-128 and RC4 against NIST test vectors for algorithm integrity, employs dynamic key rotation every 1000 encryptions to reduce key exposure risk, uses hardware-accelerated AES to counter side-channel attacks, and enforces AES-128 encryption for critical data regardless of device power constraints, thus maintaining data confidentiality consistently.

## VI. Practical Deployment Scenarios

### A. Real-World Application Matrix

Table III presents recommended cryptographic algorithms for various IoT use cases on ESP32, balancing data sensitivity and power efficiency [18] [19] [20]. Lightweight RC4 suits low-power scenarios like Smart Home Sensors and Environmental Monitoring, offering 35% and 42% power savings. Critical fields such as Industrial IoT and Security Systems prefer AES-128 for stronger security despite lower energy savings. Healthcare Devices leverage the Adaptive ESP-SecureFlow method, achieving 28% power savings while maintaining security. This highlights the trade-offs between energy consumption and cryptographic strength, stressing the importance of context-aware encryption in resource-constrained IoT devices.

TABLE III: Recommended Algorithms and Power Savings by Use Case

| Use Case | Data Type | Recommended Algorithm | Power Savings |
|---|---|---|---|
| Smart Home Sensors | Temperature readings | RC4 | 35% |
| Industrial IoT | Critical alarms | AES-128 | N/A |
| Healthcare Devices | Patient vitals | Adaptive | 28% |
| Environmental Monitoring | Routine telemetry | RC4 | 42% |
| Security Systems | Motion detection | AES-128 | N/A |

TABLE IV: Comparison of AES-128 Power Consumption and Improvement Across Platforms

| Study | Platform | AES-128 Power | Our Result | Improve--ment |
|---|---|---|---|---|
| Jin (2022) | ESP32 | 285 mAh | 268 mAh | 6.00% |
| Yasin et al. (2014) | ARM Cortex | 310 mAh | 215 mAh* | 30.60% |
| Zhou et al. (2018) | Generic IoT | 340 mAh | 215 mAh* | 36.80% |

### B. Implementation Considerations

When deploying the system, consider the following guidelines: For battery-powered devices, enable aggressive power-saving modes to maximize battery life. In always-connected systems, prioritize security measures even if they reduce power efficiency. For mixed-criticality applications, implement a message classification system to manage varying levels of urgency and importance. In edge computing scenarios, take into account the computational overhead introduced by the decision engine to maintain optimal performance.

## VII. Benchmark Comparison With Existing Work

Table IV compares AES-128 encryption power consumption across platforms, highlighting our framework's consistent energy savings of 6.00% to 36.80%. The ESP32 shows a 6.00% improvement over Jin (2022), while ARM Cortex and Generic IoT platforms achieve larger reductions of 30.60% and 36.80%, respectively. These results demonstrate our framework's adaptability and efficiency across diverse IoT architectures.

## VIII. Conclusion and Limitations

### A. Limitations

The current framework has some limitations: it adds an average decision-making latency of 0.15 ms and increases memory

Authorized licensed use limited to: Aizu University. Downloaded on September 30,2025 at 09:12:33 UTC from IEEE Xplore. Restrictions apply.

usage by 2.1KB RAM. It supports only AES-128 and RC4 algorithms. Additionally, accurate battery monitoring relies on hardware power measurement, which may be unavailable on some devices.

### B. Conclusions

This paper presents ESP-SecureFlow, an adaptive cryptographic framework that balances security and energy efficiency in IoT devices. Its dynamic algorithm selection achieves 23.8% energy savings while meeting security needs by intelligently adapting to system conditions. Evaluations show its effectiveness in various scenarios, ideal for battery-powered IoT applications requiring both security and longevity. The practical implementation targets ESP-32 systems with clear deployment guidelines. Future work includes expanding algorithm support and integrating machine learning for predictive optimization. ESP-SecureFlow marks a key advancement in energy-aware, intelligent security for the IoT ecosystem.
